The rating decision problem

Moti

- Besides *selecting* and *ranking*, the omnipresent decision problem nowadays appears to be the *rating* decision problem.
- The *rating* problem consists in *partitioning* the set of potential decision alternatives into several, usually ordered, performance categories, the definition of these categories being *intrinsic*.
- The essential *distinctive charateristics* of this kind of decision problem therefore lie in the actual definition of the rating categories.

Rating via supervised clustering or sorting

There exist two operational approaches for soving a rating problem:

- The rating categories do not explicitly refer to the actual desirability of the decision alternatives. Many rating problems in pattern and speech recognition or diagnosis are of this kind and may be solved with classification or supervised clustering algorithms. Rating categories are here usually defined with prototypical elements and rating is operated with the help of some proximity measures.
- 2. In the outranking approach, we rely instead precisely on the *desirability* of the alternatives; e.g., a credit manager may want to isolate *good* and *bad* risks, an academic department head may wish to enroll only *good* students. A crucial problem lies here in the definition of these *relational rating categories*. Here we are going to use *quantiles sorting*, e.g. *order statistics* based sorting algorithms taking into account multiple criteria performance tableaux.

Conclusi 000

Relative versus absolute rating norms

There exist two potential approaches for defining ordered rating categories:

- 1. *Relative* rating categories: The rating categories are only defined with respect to a given performance tableau and may change with each instance;
- 2. *Absolute* rating *norms*: The rating norms are defined in general and may apply to all performance tableaux of the same kind, e.g. *star rating* of hotels and restaurants, or *credit rating* of countries or companies.

Performance Quantile Classes

- We consider a series: $p_k = k/q$ for k = 0, ...q of q + 1 equally spaced quantiles like
 - quartiles: 0.00, 0.25, 0.50, 0.75, 1.00,
 - quintiles: 0.00, 0.20, 0.40, 0.60, 0.80, 1.00,
 - deciles: 0.00, 0.10, 0.20, ..., 0.90, 1.00, etc
- The upper-closed q^k class corresponds to the interval]q(p_{k-1}); q(p_k)], for k = 2, ..., q, where q(p_q) = max(X) and the first class gathers all data below p₁:] − ∞; q(p₁)].
- The lower-closed q_k class corresponds to the interval $[q(p_{k-1}); q(p_k)]$, for k = 1, ..., q 1, where $q(p_0) = \min(X)$ and the last class gathers all data above $q(p_{q-1})$: $[q(p_{q-1}), +\infty[$.
- We call *q*-tiles a complete series of *k* = 1, ..., *q* upper-closed *q^k*, resp. lower-closed *q_k*, quantile classes.

• Let X be the set of n potential decision alternatives evaluated on a single real performance criteria.

Performance Quantiles

- We denote *x*, *y*, ... the performances observed of the potential decision actions in *X*.
- We call quantile q(p) the performance such that p% of the observed *n* performances in *X* are less or equal to q(p).
- The quantile q(p) is estimated by linear interpolation from the cumulative distribution of the performances in X.

Relative *a*-tiling 0000000

Normed rating

Example

Let us consider the following 31 random performances:

1.10	6.93	8.59	20.97	22.16	24.18	25.39	27.13
32.10	32.23	33.53	34.59	38.65	41.41	41.89	44.87
45.03	50.72	50.96	54.43	58.53	59.82	61.68	62.48
64.82	65.65	71.99	80.73	87.84	87.89	91.56	-

measured on a real scale from 0.0 to 100.0.

5-tiles class limits:

Taking into account imprecise evaluations – I

Suppose now we acknowledge two preference discrimination thresholds:

- 1. An indifference threshold *ind* of 10.0 pts, modelling the maximal numerical performance difference which is considered preferentially insignificant;
- 2. A preference threshold pr of 20.0 pts (pr > ind), modelling the smallest numerical performance which is considered preferentially significant.

Upper-closed *q*-tiles sorting on a single criterion

If \mathbf{x} is a measured performance, we may distinguish three sorting situations:

If the relation < is the dual of \geq , it will be sufficient to check that both, $q(p_{k-1}) \not\ge x$, as well as $q(p_k) \ge x$, are verified for x to be a member of the k-th q-tiles class.

11/47

9/47

Multiple criteria extension

- $X = \{x, y, z, ...\}$ is a finite set of *n* objects to be sorted.
- *F* = {1, ..., *m*} is a finite and coherent family of *m* performance criteria.
- For each criterion j in F, the objects are evaluated on a real performance scale [0; M_j],
 - supporting an indifference threshold indi

and a preference threshold pr_j such that $0 \leq ind_j < pr_j \leq M_j$.

- The performance of object x on criterion j is denoted x_j .
- Each criterion j in F carries a rational significance w_j such that $0 < w_j < 1.0$ and $\sum_{j \in F} w_j = 1.0$.

The bipolar outranking relation \succsim

From an epistemic point of view, we say that:

- 1. object x outranks object y, denoted $(x \succeq y)$, if
 - 1.1 a significant majority of criteria validates a global outranking situation between *x* and *y*, and
 - 1.2 no veto is observed on a discordant criterion,
- 2. object x does not outrank object y, denoted $(x \not\gtrsim y)$, if
 - 2.1 a significant majority of criteria invalidates a global outranking situation between x and y, and
 - 2.2 no counter-veto is observed on a concordant criterion.

q-tiles sorting with bipolar outrankings

Property

The bipolar characteristic of x belonging to upper-closed q-tiles class q^k , resp. lower-closed class q_k , may hence, in a multiple criteria outranking approach, be assessed as follows:

$$r(\mathbf{x} \in \mathbf{q}^{k}) = \min \left[-r(q(p_{k-1}) \succeq \mathbf{x}), r(q(p_{k}) \succeq \mathbf{x}) \right]$$
$$r(\mathbf{x} \in \mathbf{q}_{k}) = \min \left[r(\mathbf{x} \succeq q(p_{k-1})), -r(\mathbf{x} \succeq q(p_{k})) \right]$$

The bipolar outranking relation \succsim , being weakly complete, verifies the coduality principle (Bisdorff 2013). Hence:

$$-r(q(p_{k-1}) \succeq x) = r(q(p_{k-1}) \not\preceq x) = r(q(p_{k-1}) \prec x)$$
$$-r(x \succeq q(p_k)) = (x \not\preceq q(p_k)) = r(x \prec q(p_k)).$$

The multicriteria (upper-closed) q-tiles sorting algorithm

- 1. **Input**: a set X of n objects with a performance table on a family of m criteria and a set Q of k = 1, ..., q empty q-tiles equivalence classes.
- 2. For each object $x \in X$ and each q-tiles class $q^k \in Q$ 2.1 $r(x \in q^k) \leftarrow \min(-r(q(p_{k-1}) \succeq x), r(q(p_k) \succeq x))$ 2.2 if $r(x \in q^k) \ge 0$: add x to q-tiles class q^k
- 3. Output: Q

Comment

- 1. The complexity of the q-tiles sorting algorithm is $\mathcal{O}(nmq)$; linear in the number of decision actions (n), criteria (m) and quantile classes (q).
- 2. As Q represents a partition of the criteria measurement scales, i.e. the upper limits of the preceding category correspond to the lower limits of the succeeding ones, there is a potential for run time optimization.

Properties of *q*-tiles sorting result

1. *Coherence*: Each object is always sorted into a non-empty subset of adjacent *q*-tiles classes.

Relative *q*-tiling

00000000

- 2. Uniqueness: If the q-tiles classes represent a discriminated partition of the measurement scales on each criterion and $r \neq 0$, then every object is sorted into exactly one q-tiles class.
- 3. *Independence*: The sorting result for object *x*, is independent of the other object's sorting results.

Comment

The independence property gives us access to efficient parallel processing of class membership characteristics $r(x \in q^k)$ for all $x \in X$ and q^k in Q.

Quantiles sorting example

- 34 top European Universities;
- Assessed on five cardinal criteria (measured as *z*-scores):
 - 1. Teaching: quality of the learning environment ($w_T = 3$),
 - 2. Citations: research influence ($w_C = 3$),
 - 3. Research: volume, income and reputation ($w_R = 1$),
 - 4. International outlook ($w_I = 1$),
 - 5. Industry income: innovation ($w_{Ind} = 1$).

Ordering the *q*-tiles sorting result

Normed rating

Relative q-tiling

0000000000

We may notice that some universities like 'ETHZ' and 'KIS' are sorted into several adjacent 17-tiles classes and the sorting result leaves us hence with a more or less refined partition of the set of 35 Universities.

The upper-closed 17-tiles sorting shows here 25 such overlapping quantile classes, of which 5 contain more than 1 university (1×5 , 1×3 , and 3×2 universities).

For linearly ranking from *best to worst* these 25 quantile classes we may apply three strategies:

- 1. Optimistic: In decreasing lexicographic order of the *upper* and *lower* quantile class limits;
- 2. Pessimistic: In decreasing lexicographic order of the *lower* and *upper* quantile class limits;
- 3. Average (default): In decreasing numeric order of the *average* of the lower and upper quantile limits. In case of ties, we select first the *highest upper* quantile class.

Quantiles sorting on a single criterion Multiple criteria *q*-tiles sorting

3. Absolute rating with quantile norms

Learning rating quantile norms Rating by ranking decision actions and quantile limits Showing rating results

Normed (learned) quantiles rating

Normed rating

0000000000

Decision problem: Rating multiple criteria performances with respect to historical order statistics, i.e. performance quantiles learned from historical data gathered in the past.

Example (How to rate two decision actions - I)

Consider below the multi-criteria performances of two potential decision actions named a1001 and a1010:

Criterion	b1	b2	b3	b4	b5	c1	с2
Weight	2	2	2	2	2	5	5
a1001	37.0	2	2	61.0	31.0	-4	-40.0
a1010	32.0	9	6	55.0	51.0	-4	-35.0

Both are evaluated on 7 seven performance criteria: five *Benefits* criteria: b1 to b5 (objective to maximize) and two Costs criteria: c1 and c2 (objective to *minimize*).

		25 / 47				26 / 47
Relative q-tiling 0000000 000 000000000	Normed rating 00●00000000 0000000000000000000000000	Conclusion 000	Motivation O O	Relative q-tiling 0000000 000 000000000	Normed rating 0000000000 000000 000	Conclusion 000

Absolute versus relative rating

Example (How to rate two decision actions – III)

When compared with all similar multi-criteria performances one has meanwhile already encountered, how may the multiple criteria performances of a1001, respectively a1010, now be rated ?

Criterion	b1	b2	b3	b4	b5	c1	c2
Weight	2	2	2	2	2	5	5
a1001	37.0	2	2	61.0	31.0	-4	-40.0
a1010	32.0	9	6	55.0	51.0	-4	-35.0

Excellent, good, or fair ?

Perhaps even, weak or very weak ?

Example (How to rate two decision actions - II)

• The performances on the *Costs* criterion *c*² are measured on an ordinal negative scale from -10 (worst) to 0 (best), whereas the performances on the Costs criterion c2 are measured on a cardinal negative scale from -100.00 (worst) to 0.0 (best).

Absolute versus relative rating

- The performances on the *Benefits* criteria b2 and b3 are measured on an ordinal positive scale from 0 (worst) to 10 (best), whereas the performances on the Benefits criteria b1, b4 and b5 are measured on a cardinal scale from 0.0 (worst) to 100.0 (best).
- The *importance* (sum of weights) of the 2 *Costs* criteria is equal to the importance (sum of weights) of the 5 Benefits criteria.

Incremental learning of quantiles

The PerformanceQuantiles class (see performanceQuantiles module) estimates performance quantiles from a performance tableau instance.

Its main components are:

- Ordered objectives and criteria dictionaries copied from the given performance tableau instance;
- A list called quantileFrequencies, with a complete set of quantile frequencies, like *quartiles* [0.0, 0.25, 05, 0.75, 1.0], *quintiles* [0.0, 0.2, 0.4, 0.6, 0.8, 1.0] or *deciles* [0.0, 0.1, 0.2, ..., 1.0] for instance;
- An ordered limitingQuantiles dictionary with so far estimated *lower* (default) or *upper* quantile class limits for each frequency per criterion;
- An ordered **historySizes** dictionary keeping track of the number of evaluations seen so far per criterion. Missing data may make these sizes vary from criterion to criterion.

Using the PerformanceQuantiles class - continue

The constructor parameter numberOfBins, choosing the wished number of quantile frequencies, may be either *quartiles* (4 bins), *quintiles* (5 bins), *deciles* (10 bins), *dodeciles* (20 bins) or any other integer number of quantile bins. The quantile bins may be either lower closed (default) or upper-closed.

Using the PerformanceQuantiles class

Example Python session:

>>> from performanceQuantiles import PerformanceQuantiles
>>> from randomPerfTabs import RandomCBPerformanceTableau
>>> tp = RandomCBPerformanceTableau(numberOfActions=900,\
numberOfCriteria=7,seed=100)
>>> pq = PerformanceQuantiles(tp, numberOfBins = 'quartiles',\
LowerClosed=True)
>>> pq
* PerformanceQuantiles instance description*
Instance class : PerformanceQuantiles
Instance name : 4-tiled_performances
<pre># Objectives : 2, # Criteria : 7, # Quantiles : 4</pre>
History sizes : {'c1': 887, 'b1': 888, 'b2': 891, 'b3': 895,
'b4': 892, 'c2': 893, 'b5': 887}
Attributes : ['perfTabType', 'valueDigits',
'actionsTypeStatistics', 'objectives',
'BigData', 'missingDataProbability',
'criteria', 'LowerClosed', 'name',
'quantilesFrequencies', 'historySizes',
'limitingQuantiles', 'cdf']

We suppose that the decision alternatives a1001 and a1010, seen before, are indeed drawn from the same tp random performance tableau model.

Normed rating

000000000000

Using the PerformanceQuantiles class - continue

Relative q-tiling

- The preference direction of the *Costs* criteria is *negative*; the lesser the costs the better it is, wheras all the *Benefits* criteria: *b*1 to *b*5 show *positive* preference directions, i.e. the higher the benefits the better it is.
- The columns entitled '0.00', resp. '1.00' show the quartile Q₀, resp. Q₄, ie the *worst*, resp. *best* performance observed so far on each criterion. Column '0.50' shows Q₂, the median performance observed on the criteria.
- The random performances on all criteria appear to be more or less symmetrically distributed around median scales values (-50.0, 5, 50.0) with a spread of approximatively 20% of the scale's amplitude.

Generating new random data

New decision actions with random multiple criteria performance vectors from the same random performance tableau model may now be generated with ad hoc random performance generators. We provide, for experimental purpose, in the randomPerfTabs module a generic RandomPerformanceGenerator for three models of random performance tableaux:

- The standard RandomPerformanceTableau model,
- The two objectives RandomCBPerformanceTableau Cost-Benefit model, and
- The Random30bjectivesPerformanceTableau model with three objectives concerning respectively economic, environmental and societal aspects.
- >>> # generate 100 new random decision actions
- >>> from randomPerfTabs import RandomPerformanceGenerator
- >>> rpg = RandomPerformanceGenerator(tp,seed=seed)
- >>> newTab = rpg.randomPerformanceTableau(100)

Updating the historical quantile limits

Given a new performance tableau *newTab* with 100 new decision alternatives. the so far estimated historical quantile limits may be updated as follows:

>>> # Updating the quartile norms shown above

- >>> pq.updateQuantiles(newTab, historySize=None)
 - Parameter historySize of the pg.updateQuantiles() method allows to balance the new evaluations against the historical ones.
 - With **historySize** = None (the default setting), the balance in the example above is 900/1000 (90%, weight of historical data) against 100/1000 (10%, weight of the new incoming observations).
 - Putting historySize = 0, for instance, will ignore all historical data (0/100 against 100/100) and restart building the quantile estimation with solely the new incoming data.

	Motivation	Relative q-tiling	Normed rating	Conclusion
imits	0	0000000	0000000000 000000	000

The NormedQuantilesRatingDigraph class

- For absolute rating of a newly given set of decision actions, we provide, in the sortingDigraphs module, the NormedQuantilesRatingDigraph class, a specialisation of the SortingDigraph class.
- The class constructor requires a valid PerformanceQuantiles instance (pq) and a compatible PerformanceTableau instance (newTab) or a dictionary newActions with compatible new decision alternatives.
- The actions dictionary in such a

NormedQuantilesRatingDigraph class instance will contain not only newly given decision alternatives, but also the estimated quantile bins' performance limits from a given PerformanceQuantiles instance.

Showing the historical quantile

The updated quantile limits may be shown in a browser view.

- >>> # browsing the updated quantile limits
- >>> pq.showHTMLLimitingQuantiles(Transposed=True)

Performance quantiles

Sampling sizes between 986 and 995.

Using the NormedQuantilesRatingDigraph class

Data input to the *NormedQuantilesRatingDigraph* class constructor provides a set, called *newActions*, of new decision alternatives generated from the same random model.

>>> nqr.showHTMLPerformanceTableau(actionsSubset = nqr.newActions)

criteria	b1	b2	b3	b4	b5	c1	c2
weight	2.00	2.00	2.00	2.00	2.00	5.00	5.00
a1001c	37.00	2.00	2.00	61.00	31.00	-4.00	-40.00
a1002c	27.00	5.00	4.00	54.00	63.00	-6.00	-23.00
a1003a	24.00	8.00	2.00	74.00	61.00	-8.00	-37.00
a1004c	16.00	3.00	1.00	25.00	48.00	-5.00	-37.00
a1005c	42.00	3.00	6.00	28.00	30.00	-1.00	-24.00
a1006c	33.00	3.00	3.00	20.00	39.00	-5.00	-27.00
a1007c	39.00	6.00	2.00	20.00	16.00	-1.00	-73.00
a1008n	64.00	5.00	6.00	49.00	96.00	-6.00	-43.00
a1009n	42.00	4.00	6.00	44.00	57.00	-6.00	-94.00
a1010n	32.00	9.00	6.00	55.00	51.00	-4.00	-35.00

Among the 10 new incoming decision actions (see above) there appear the two decision actions a1001 and a1010 mentioned in the beginning.

tivation	Relative q-tiling	Normed rating	Conclusion	Motivation	Relative q-tiling	Normed rating	Conclusi
	0000000 000 00000000	000000000 000000 000	000	0 0 0	0000000 000 00000000	000000000 000000 000	000

Using the NormedQuantilesRatingDigraph class

The NormedQuantilesRatingDigraphdigraph instance's actions dictionary also contains the closed lower limits of the four quartile classes: m1 = [0.0 - 0.25[, m2 = [0.25 - 0.5[, m3 = [0.5 - 0.75[, and m4 = [0.75 - 1.0[.

>>> nqr.showPerformanceTableau(actionsSubset=nqr.profiles)

*	per	formance	tableau	*		
criteri	ia	'm1'	'm2'	'm3'	'm4'	
'b1'	I	2.0	28.8	49.6	75.3	
'b2'	I	0.0	2.9	4.9	6.7	
'b3'	I	0.0	2.9	4.9	8.0	
'b4'	I	3.3	35.9	58.6	72.0	
'b5'	I	0.8	32.8	48.1	69.7	
'c1'	I	-10.0	-7.4	-5.4	-3.4	
'c2'	1	-96.4	-72.2	-52.3	-34.0	

Ranking decision actions and quantile limits

- The actual rating procedure will rely on a linear ranking of the *new decision actions* and the *quantile class limits* obtained from the corresponding bipolar valued outranking digraph.
- Two *efficient and scalable* ranking rules, the Copeland rule and, its valued version, the Netflows rule may be used for this purpose.
- The rankingRule Parameter allows to choose one of both. With rankingRule = 'best' (see Line 4 above) the NormedQuantilesRatingDigraph constructor will choose the ranking rule that results in the highest ordinal correlation with the given outranking relation.
- In this rating example, the Copeland rule appears to be the *more appropriate* ranking rule.

Ranking decision actions and quantile limits

```
>>> nqr.rankingRule
 'Copeland'
>>> ngr.actionsRanking
 ['m4', 'a1005', 'a1010', 'a1002', 'a1008', 'a1006',
  'a1001', 'a1003', 'm3', 'a1004', 'a1007', 'a1009',
  'm2', 'm1']
>>> ngr.showCorrelation(ngr.correlation)
 Correlation indexes:
  Crisp ordinal correlation : +0.945
  Epistemic determination
                              : 0.522
  Bipolar-valued equivalence : +0.493
```

We achieve here a linear ranking without ties (from best to worst) of the new decision actions as well as the quartile limits m1 to m4, which is very close in an ordinal sense ($\tau = +0.94$) to the underlying outranking relation.

Showing rating results

The eventual rating procedure is based on the lower quantile limits, such that we may collect the quartiles' contents in increasing order of the quartiles' lower limits.

```
>>> nqr.ratingCategories
OrderedDict([
('m2', ['a1004', 'a1007', 'a1009']),
('m3', ['a1001', 'a1002', 'a1003', 'a1005', 'a1006', 'a1008', 'a1010'])
1)
```

We notice above that no decision action is rated in the highest quartile class [0.75 -1.0] or in the lowest quartile class [0.0 - 0.25]. Indeed, the rating result is shown in descending order as follows.

```
>>> nqr.showQuantilesRating()
*----- Quantiles rating result ------
[0.50 - 0.75[ ['a1001', 'a1002', 'a1003', 'a1005',
               'a1006', 'a1008', 'a1010']
[0.25 - 0.50[ ['a1004', 'a1007', 'a1009']
```

Reconsidering the question at the beginning of the lecture, we may now see that in view of our historical recordings, both decision action a1001 and a1010 are actually rated in quartile Q3 ([0.50-0.75]).

Conclusion

In this presentation, we addressed the problem of rating multiple criteria performances of a set of potential decision actions with respect to empirical order statistics, i.e. performance quantiles learned from historical performance data gathered from similar decision actions observed in the past.

Example (How to rate two decision actions - continue)

Absolute	Criterion	b1	b2	b3	b4	b5	c1	c2
Rating	Weight	2	2	2	2	2	5	5
[0.50 - 0.75]	a1001 <i>c</i>	37.0	2	2	51.00	31.00	-4	-40.00
[0.50 - 0.75]	a10010 <i>n</i>	32.0	9	6	55.00	51.00	-4	-35.00
